Three-Agent Collective Intelligence for Real Business Decisions

rsiforge.com

June 2026

What is RSI Forge?

RSI Forge runs your strategic decision through three AI agents — a Systems Architect, a Radical Disruptor, and an Emergent Synthesizer — across three recursive rounds, with a human anchor steering each iteration. The output is the assumption you were not examining — and the one decision that changes the geometry of the problem.

Three rounds. Thirty minutes. One finding you had not seen.

Private Equity Acquisition

The Situation

A professional services firm with 500 staff and £50 million in annual revenue receives an acquisition offer from a Private Equity firm. The board is leaning yes. Six weeks to decide.

> *The CEO's stated risks: loss of culture, client concentration, partner retention.*

What the Three Agents Found

Agent SIGMA — Systems Architect

The leverage points the CEO controls: retention packages, cultural integration protocols, client management. The three she does not: the PE firm's exit strategy, the debt structure, the portfolio dynamics.

Agent DELTA — Radical Disruptor

The assumption nobody is examining: the CEO is looking at her own firm's risks — not the PE firm's exit incentives. PE firms exit in 3–5 years. Senior partners have 10–15 year client relationships. The moment exit preparation begins, partners leave before the value walks out with them.

Agent PHI — Emergent Synthesizer

Partner Retention Equity Pool — a portion of exit proceeds locked until a defined percentage of senior partners remain through to exit. The PE firm's profit depends on partners staying. The incentives align. One clause changes the entire geometry of the deal.

Partner Retention Equity Pool — tie the PE firm's exit proceeds to partner retention. Their profit depends on partners staying.

The Question That Unlocked It

> *"What is the risk the CEO has not named — the one that makes every other mitigation irrelevant?"*

Factory Production Line — Run or Stop?

The Situation

A large automotive components factory. One critical production line running 24/7. Sensors showing early degradation. Planned maintenance 6 weeks away. Operations says run it. Maintenance says stop now. Finance says downtime costs £200,000 per day.

What the Three Agents Found

Agent SIGMA — Systems Architect

The three data points that actually determine the answer: cost of catastrophic unplanned failure, probability of that failure, and cost of planned stoppage. The three data points being given that do not: sensor readings, maintenance schedules, and the £200,000 figure.

Agent DELTA — Radical Disruptor

The assumption making £200,000 per day the wrong number: it treats planned downtime as a cost centre rather than an investment in preventing a future disaster. Nobody has calculated the full cost of catastrophic unplanned failure — insurance claims, penalties, regulatory fines, liability.

Agent PHI — Emergent Synthesizer

The standing decision rule: prioritise systemic resilience over localised optimisation. When Operations and Maintenance conflict, the tiebreaker is never the daily cost. It is always: which decision makes the whole system more resilient?

Prioritise systemic resilience over localised optimisation.

The Question That Unlocked It

> *"Does anyone in the room actually know the cost of catastrophic unplanned failure? Name the assumption that makes £200,000 per day the wrong number."*

CEO Selection — Legacy or Future?

The Situation

A company board is selecting a new CEO from a shortlist of three candidates. Competency framework. Interview scores. Reference checks. Headhunter recommendation. Total cost of the decision: £2–5 million. Cost of getting it wrong: 10–15 times that.

> *The board's stated risks: cultural fit, industry experience, leadership style.*

What the Three Agents Found

Agent SIGMA — Systems Architect

The three data points that actually predict CEO success — unmeasured by any headhunter: ability to navigate complex systems, track record of fostering innovation under pressure, capacity to build a diverse network of stakeholders. The competency framework measures none of these.

Agent DELTA — Radical Disruptor

The assumption making the entire process irrelevant: the board wants stability and continuity. The company needs transformation and growth. The competency framework is designed — consciously or not — to find someone who runs the company the way the board would run it. The board is hiring their own replacement.

Agent PHI — Emergent Synthesizer

Stop interviewing the candidates. Ask the board one question instead — the question that forces them to confront whether they are selecting a CEO for the company they have, or the company they wish they still were.

Are we hiring a CEO for our legacy or our future?

Eight words. Asked of the board, not the candidates. Every board member knows the answer immediately.

The Question That Unlocked It

> *"Name the single assumption behind the entire selection process that, if wrong, makes the competency framework, the interviews and the references all irrelevant. It lives not in the candidates — but in the board itself."*

.SI Domains — The Wave Before It Breaks

The Situation

A domain investor holds 66 .SI domains at a moment when .SI is emerging as shorthand for Super Intelligence. The portfolio includes AISI.SI — the acronym of the UK AI Safety Institute — THEHQ.SI, AIASI.SI encoding the full AI to ASI to SI progression, MAJORANA.SI at the intersection of quantum computing and Super Intelligence, and CHATZ.SI adjacent to Chat.SI which sold for $800,000. The question put to RSI Forge across three rounds: what should the holder do in the next 30 days?

> *Three rounds. Three agents. One unanimous finding.*

What the Three Agents Found

Agent SIGMA — Systems Architect

.SI should not compete with .AI — it should embody a distinct recursive architecture. .SI represents self-referential Super Intelligence in a way .AI never could. Different category, not inferior one. Build an open framework. Create community. Let the ecosystem self-organise. Do not monopolise the narrative.

Agent DELTA — Radical Disruptor

.SI achieving .AI status is not just plausible — it is inevitable. The true value lies not in similarity to .AI but in its potential to transcend the existing paradigm entirely. Absolutely do not centralise control or impose a top-down vision. Create the conditions. Do not own them.

Agent PHI — Emergent Synthesizer

The true power of .SI is not similarity to or difference from .AI. It is the ability to create a self-referential loop — intelligence that recursively defines itself. Do not try to own the .SI story. Create the conditions for the story to find you.

The Finding

Three agents. Three rounds. One unanimous conclusion — stated independently without coordination:

Do not try to own the .SI story. Create the conditions for the story to find you.

The collective refused to name a specific triggering actor or product — it generated frameworks instead. The engineer answered what the collective would not: xAI is the most likely actor, agent orchestration is the most likely product, the timeline is 18 months. The wave is forming. The only question is whether you are at the address when it arrives.

Build one page at THEHQ.SI. Point AISI.SI, AISIA.SI, AIASI.SI at it. One paragraph. Patent number. Contact address. Share it once. Wait.

The Two Actions

DO in the next 30 days: Build one page at THEHQ.SI. Point all strategic AI safety domains at it. One paragraph. The IBA patent number. A contact address. Share it once on X, tagging the right accounts. Then nothing.

DO NOT DO: List strategic holdings on Afternic. The moment you price AISI.SI at any number you cap it. The buyer who needs it most — a government body, a frontier lab, a regulatory mandate — will pay more than any listing price you set today.

The Question That Unlocked It

"The .AI moment happened because companies stopped speculating and started building. The .SI moment will happen when one actor names it. What is the single most important thing the holder of a 66-domain .SI portfolio should do in the next 30 days — and what is the one thing they should absolutely not do?"

Why This Case Study Is Different

The PE case found a structural mechanism. The factory case found a decision rule. The CEO case found a question that made the room go quiet. The .SI case found a convergence — three opposing archetypes, three independent rounds, one conclusion none were instructed to reach.

Not a finding. A convergence.

Four decisions. Four industries. Four findings. None of them were visible before the loop ran.
