Three-Agent Collective Intelligence for Real Business Decisions

rsiforge.com

May 2026

What is RSI Forge?

RSI Forge runs your strategic decision through three AI agents with distinct archetypes — a Systems Architect, a Radical Disruptor, and an Emergent Synthesizer — across three recursive rounds, with a human anchor steering each iteration. The output is not a report. It is the assumption you were not examining — and the one decision that changes the geometry of the problem.

Three rounds. Thirty minutes. One finding you had not seen.

How It Works

RSI Forge is built on a simple but powerful architecture:

Agent SIGMA — Systems Architect

Maps the full structure of the decision. Identifies what must be simultaneously true for each option to be correct. Finds the leverage points the CEO controls — and the ones she does not.

Agent DELTA — Radical Disruptor

Challenges every assumption. Names the risk nobody in the room is examining. Identifies what must be destroyed for the plan to fail.

Agent PHI — Emergent Synthesizer

Reads what SIGMA and DELTA produced before responding. Discovers the path that neither could reach alone — the deal structure, the decision rule, the clause that changes everything.

The Human Anchor

Between each round, you steer. You agree, redirect, escalate, or inject a constraint. Your input seeds the next round. The loop does not run without you — and it produces something different every time because of you.

What It Produces

A session export documenting every agent response and every human anchor. A one-page summary of the finding. The assumption that was not being examined. The decision, clause, or rule that changes the geometry of the problem.

Private Equity Acquisition

The Situation

A professional services firm with 500 staff and £50 million in annual revenue receives an acquisition offer from a Private Equity firm — an investor that buys companies, restructures them, and sells them for a profit, typically within 3-5 years. The CEO's board is leaning yes. The decision must be made in 6 weeks.

The CEO's stated risks: loss of culture, client concentration, partner retention.

What the Three Agents Found

Agent SIGMA — Systems Architect

The structural dependencies: for the acquisition to create value, the PE firm's investment horizon must align with the firm's relationship timeline. The three leverage points the CEO controls: retention packages, cultural integration protocols, client relationship management. The three she does not: the PE firm's exit strategy, the debt structure, the portfolio dynamics.

Agent DELTA — Radical Disruptor

The assumption nobody is examining: the CEO is looking at her own firm's risks. She is not looking at the PE firm's exit incentives. PE firms exit in 3-5 years. Senior partners have 10-15 year client relationships. The moment exit preparation begins, partners can see it coming — and leave before the value walks out with them.

Agent PHI — Emergent Synthesizer

The hidden third path: a Partner Retention Equity Pool — a portion of exit proceeds locked in a pool that is only accessible if a defined percentage of senior partners remain with the firm through to exit. The PE firm's profit depends on partners staying. The incentives align. One clause changes the entire geometry of the deal.

The Finding

The CEO was not looking at the PE firm's exit incentives. She was looking at her own firm's risks. These are two completely different problems.

The mechanism that makes culture, clients and partners irrelevant simultaneously: PE firms exit in 3-5 years. Professional services relationships take 10-15 years to build. When exit preparation begins, senior partners leave before the value walks out with them. No retention package, cultural protocol, or client management strategy prevents this — because the incentive to leave exists regardless.

Partner Retention Equity Pool — tie the PE firm's exit proceeds to partner retention. Their profit depends on partners staying. The incentives align.

The Question That Unlocked It

Round 2 anchor: "What is the risk the CEO has not named — the one that, if it materialises, makes every other mitigation irrelevant?"

Factory Production Line — Run or Stop?

The Situation

A large automotive components factory. One critical production line running 24 hours a day, 7 days a week. Sensors are showing early degradation signals on a key piece of equipment. Planned maintenance is 6 weeks away. The CEO must decide by end of week.

Operations says run it. Maintenance says stop now. Finance says the line going down costs £200,000 per day.

What the Three Agents Found

Agent SIGMA — Systems Architect

The three data points that actually determine the answer: the cost of catastrophic unplanned failure, the probability of that failure occurring, and the cost of a planned stoppage. The three data points the CEO is being given that do not determine the answer: sensor degradation readings, maintenance schedules, and the £200,000 per day downtime figure.

Agent DELTA — Radical Disruptor

The assumption making £200,000 per day the wrong number: it treats planned downtime as a cost centre rather than an investment in preventing a future disaster. Nobody in the room has calculated the full cost of catastrophic unplanned failure — insurance claims, customer contract penalties, regulatory fines, reputational damage, potential personal liability. Until you know that number, every decision is made against the wrong denominator.

Agent PHI — Emergent Synthesizer

The standing decision rule that makes this conflict impossible next time: Prioritise systemic resilience over localised optimisation. When Operations and Maintenance conflict, the tiebreaker is never the daily cost figure. It is always: which decision makes the whole system more resilient? Planned stoppage is resilience. Catastrophic failure is not.

The Finding

The £200,000 per day figure was driving the entire conversation — but it was the wrong number. It measures the cost of a planned decision. It does not measure the cost of the alternative.

The full cost of catastrophic unplanned failure in a manufacturing environment typically includes: weeks of unplanned downtime, emergency repair costs, scrapped product, customer contract penalty clauses, insurance excess, regulatory investigation, reputational damage with tier-1 customers, and in the worst case, personal liability for directors. That number is rarely calculated in

advance. When it is, planned maintenance almost always wins.

Prioritise systemic resilience over localised optimisation.

Nine words. Goes on the wall. Changes every future conflict between Operations, Maintenance and Finance.

The Question That Unlocked It

Round 2 anchor: "The CEO is being shown £200,000 per day. Does anyone in the room actually know the cost of catastrophic unplanned failure? Name the assumption that makes £200,000 per day the wrong number to be looking at."

What RSI Forge Is For

RSI Forge is not a research tool. It is not a report generator. It is a decision stress-test.

It is most useful when:

A major decision is being made under time pressure

Acquisition, market entry, technology bet, restructuring. The loop surfaces the assumption being made under pressure that nobody has examined.

Two departments are in conflict

Operations vs Maintenance. Finance vs Strategy. The loop finds the decision rule that makes the conflict impossible — not the compromise that satisfies nobody.

The risks are known but the geometry feels wrong

The CEO knows the risks. The loop finds the risk she has not named — the one that makes all the others irrelevant if it materialises.

A deal needs a clause that aligns incentives

The loop finds the structural mechanism — the pool, the threshold, the condition — that changes whose interests point in the same direction.

The Format

One session. Three rounds. Thirty minutes of your time as the human anchor.

Round 1: You describe the decision. SIGMA maps the structure. DELTA names the danger. PHI finds the path.

Round 2: You anchor with the real question — the one the agents have not yet answered. The loop tightens.

Round 3: PHI produces the mechanism — the clause, the rule, the decision that changes the geometry.

Deliverable: Session export with every agent response. One-page summary. The finding in one sentence.

Every decision is different. Every loop produces something the CEO had not seen.
